

ASSIGNMENTS – OOADI

LECTURE 10

1. Consider the client code from previous course module exercise, what type of errors can you envision? Write at least three fault possibilities
2. Repeat with the server-side code that you may have. Write at least three fault possibilities
3. Some of the above faults and errors you are probably already catching. Consider by design, what to do when entering those fault conditions. Anything you can change from standard output to actual sensible behavior beside stopping some functionality?
4. Some faults you may not have covered by default. Define your own exceptions for those types of faults and address them in your code. Think about for example
 - a. A search for a specific train type most likely just lead to a null pointer exception, but that is not useful. Creating a `TrainNotFoundException` may be a more intuitive way to indicate and catch faults. But is it really a fault and if so, what type is it?
 - b. If your communication only allows, say 100 train descriptions to be send back in a single response, an error could also be that too many trains were found. How can you address this?
